Personal fees and educational grants from:

Abbott Diabetes Care, Ascensia, NovoNordisk, Eli Lilly, Sanofi, MSD, Boehringer Ingelheim, Napp Pharma, Roche (Accu Chek), BioEpic

Learning objectives

- Understand the impact of glucose variability and its common causes
- How to identify variability
- How to reduce variability

Association of British Clinical Diabetologists

Why is glucose variability important?

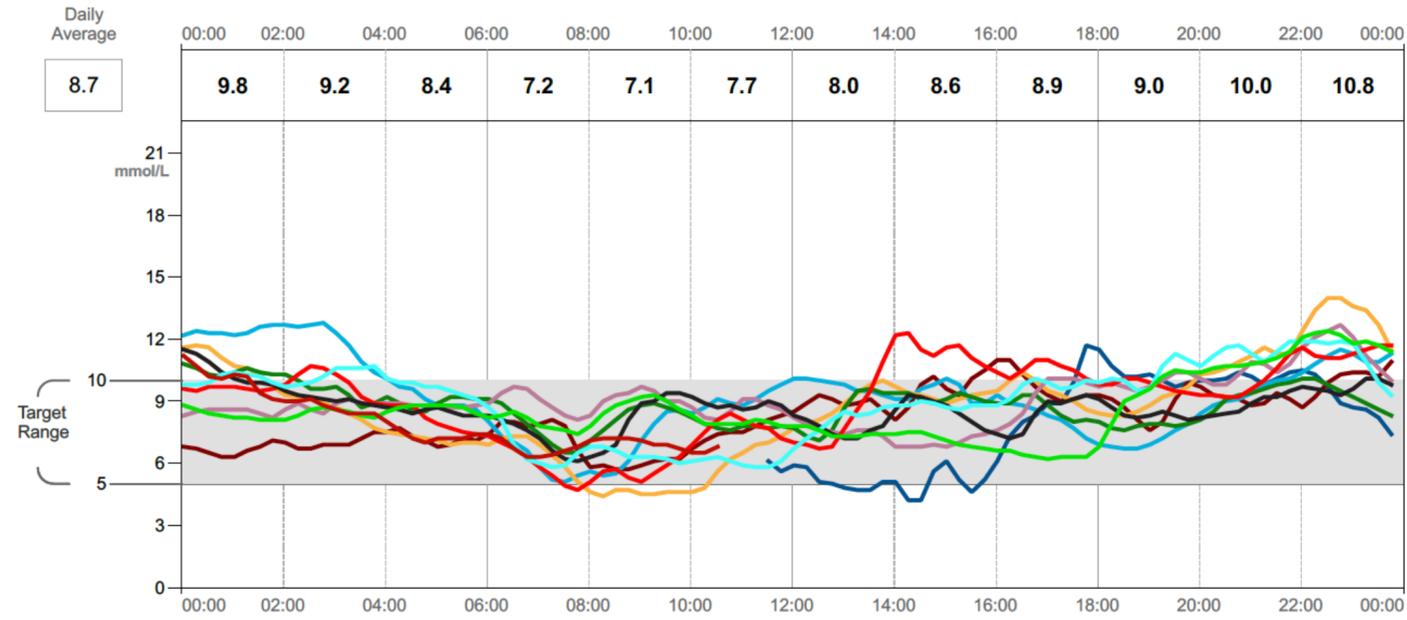

- Traditional measures of glucose control (eg HbA1c) tend to rely on the overall average glucose level
- To achieve a reduction in this average (and so reduce "exposure" to excessive glucose levels) is often seen as the goal of therapy
- However, undue focus on the average can lead to problems with hypoglycaemia if the differences in glucose levels between one day and another (variability) are not addressed

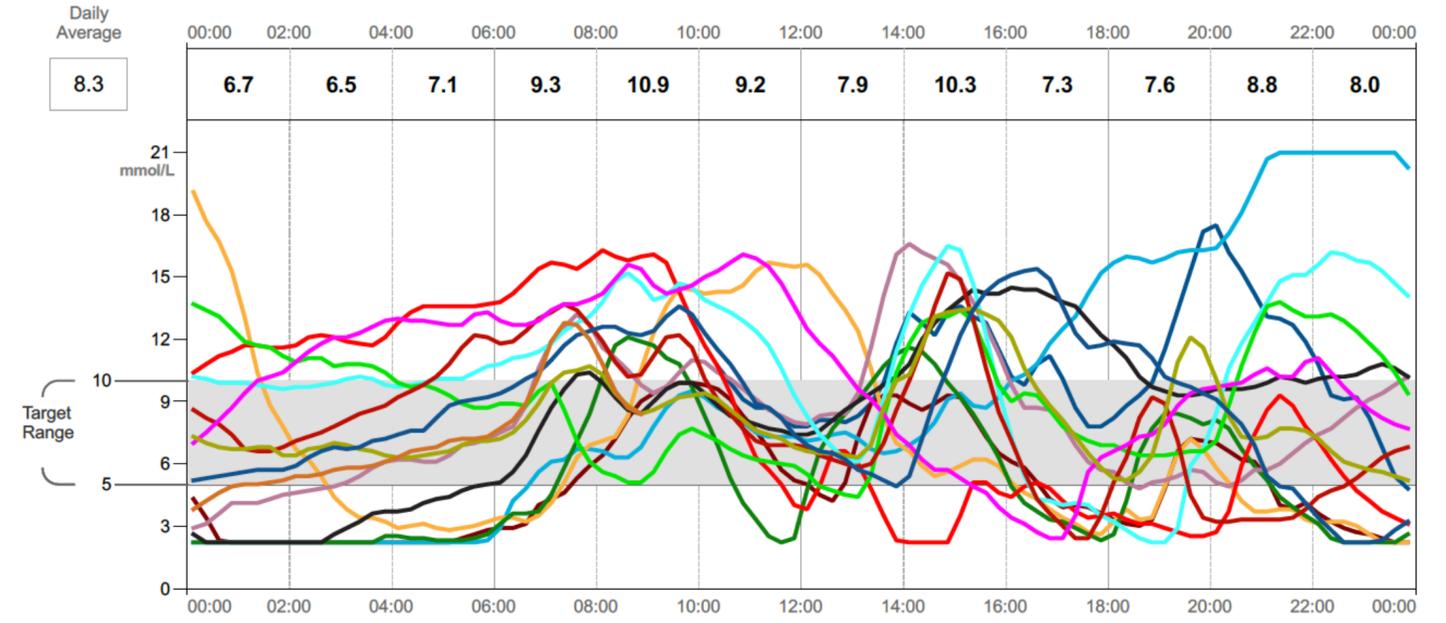

Association of British Clinical Diabetologists

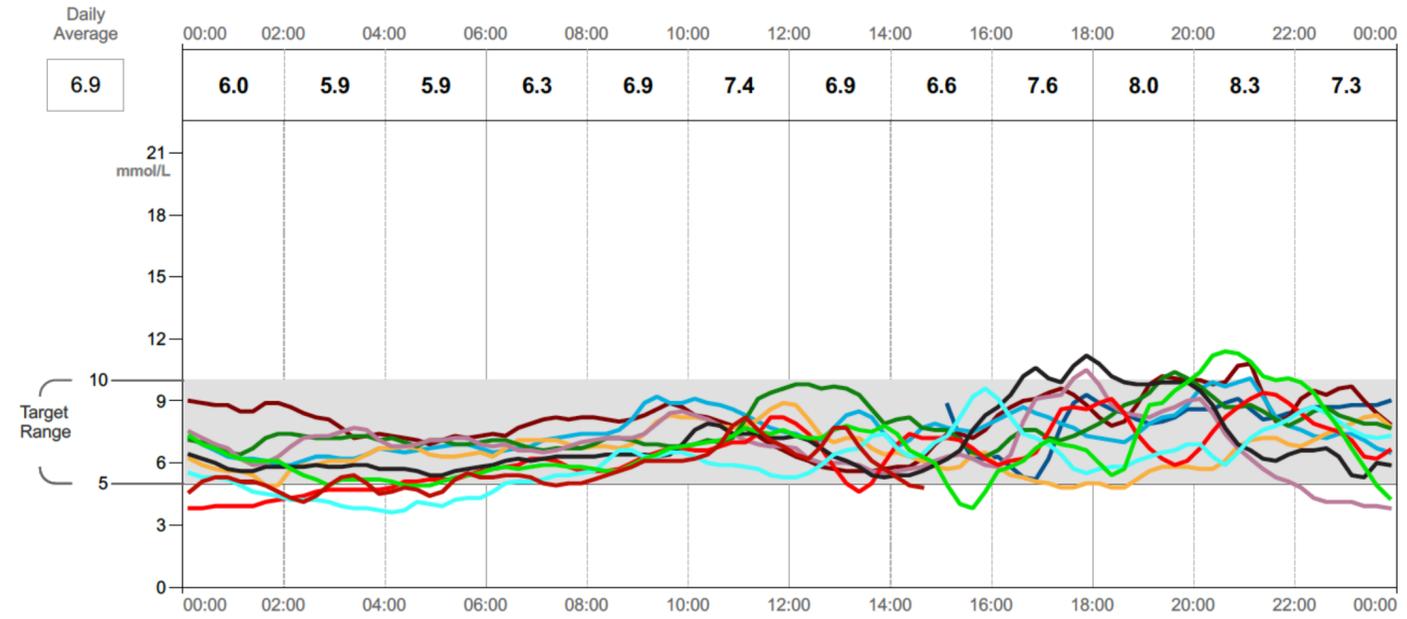

Estimated A1c 7.1% or 54 mmol/mol

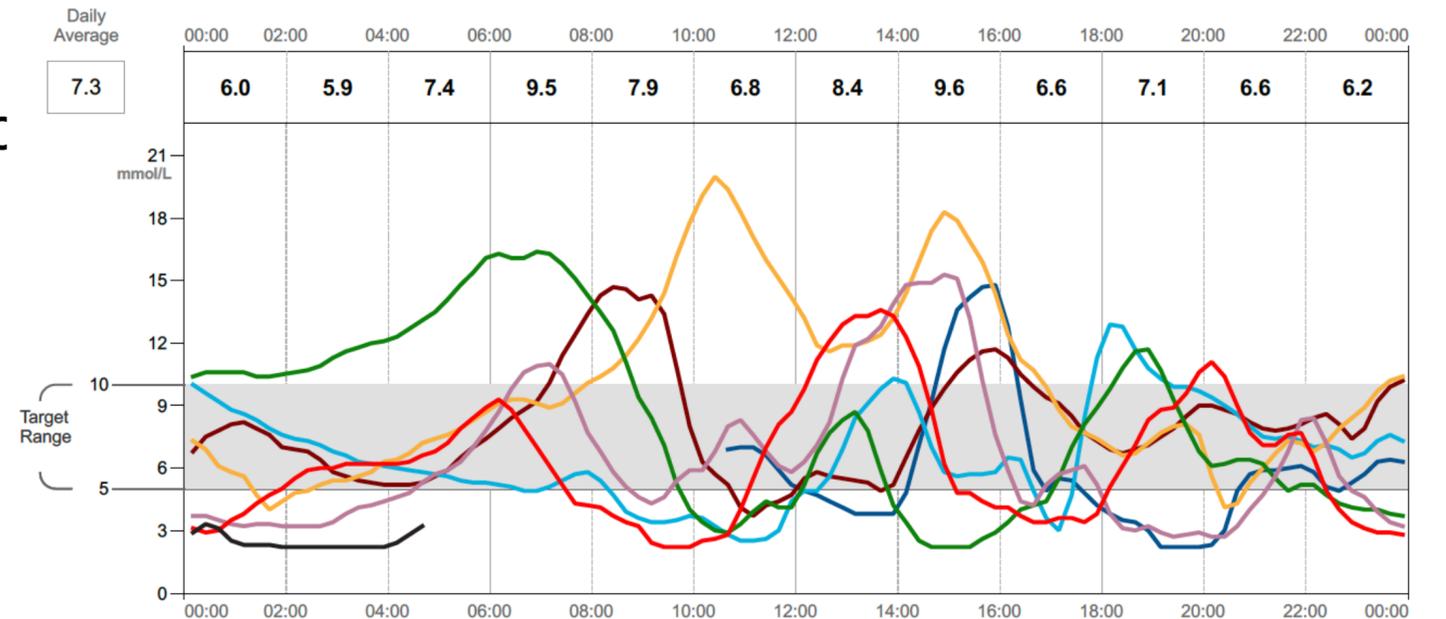

Estimated A1c 6.8% or 51 mmol/mol

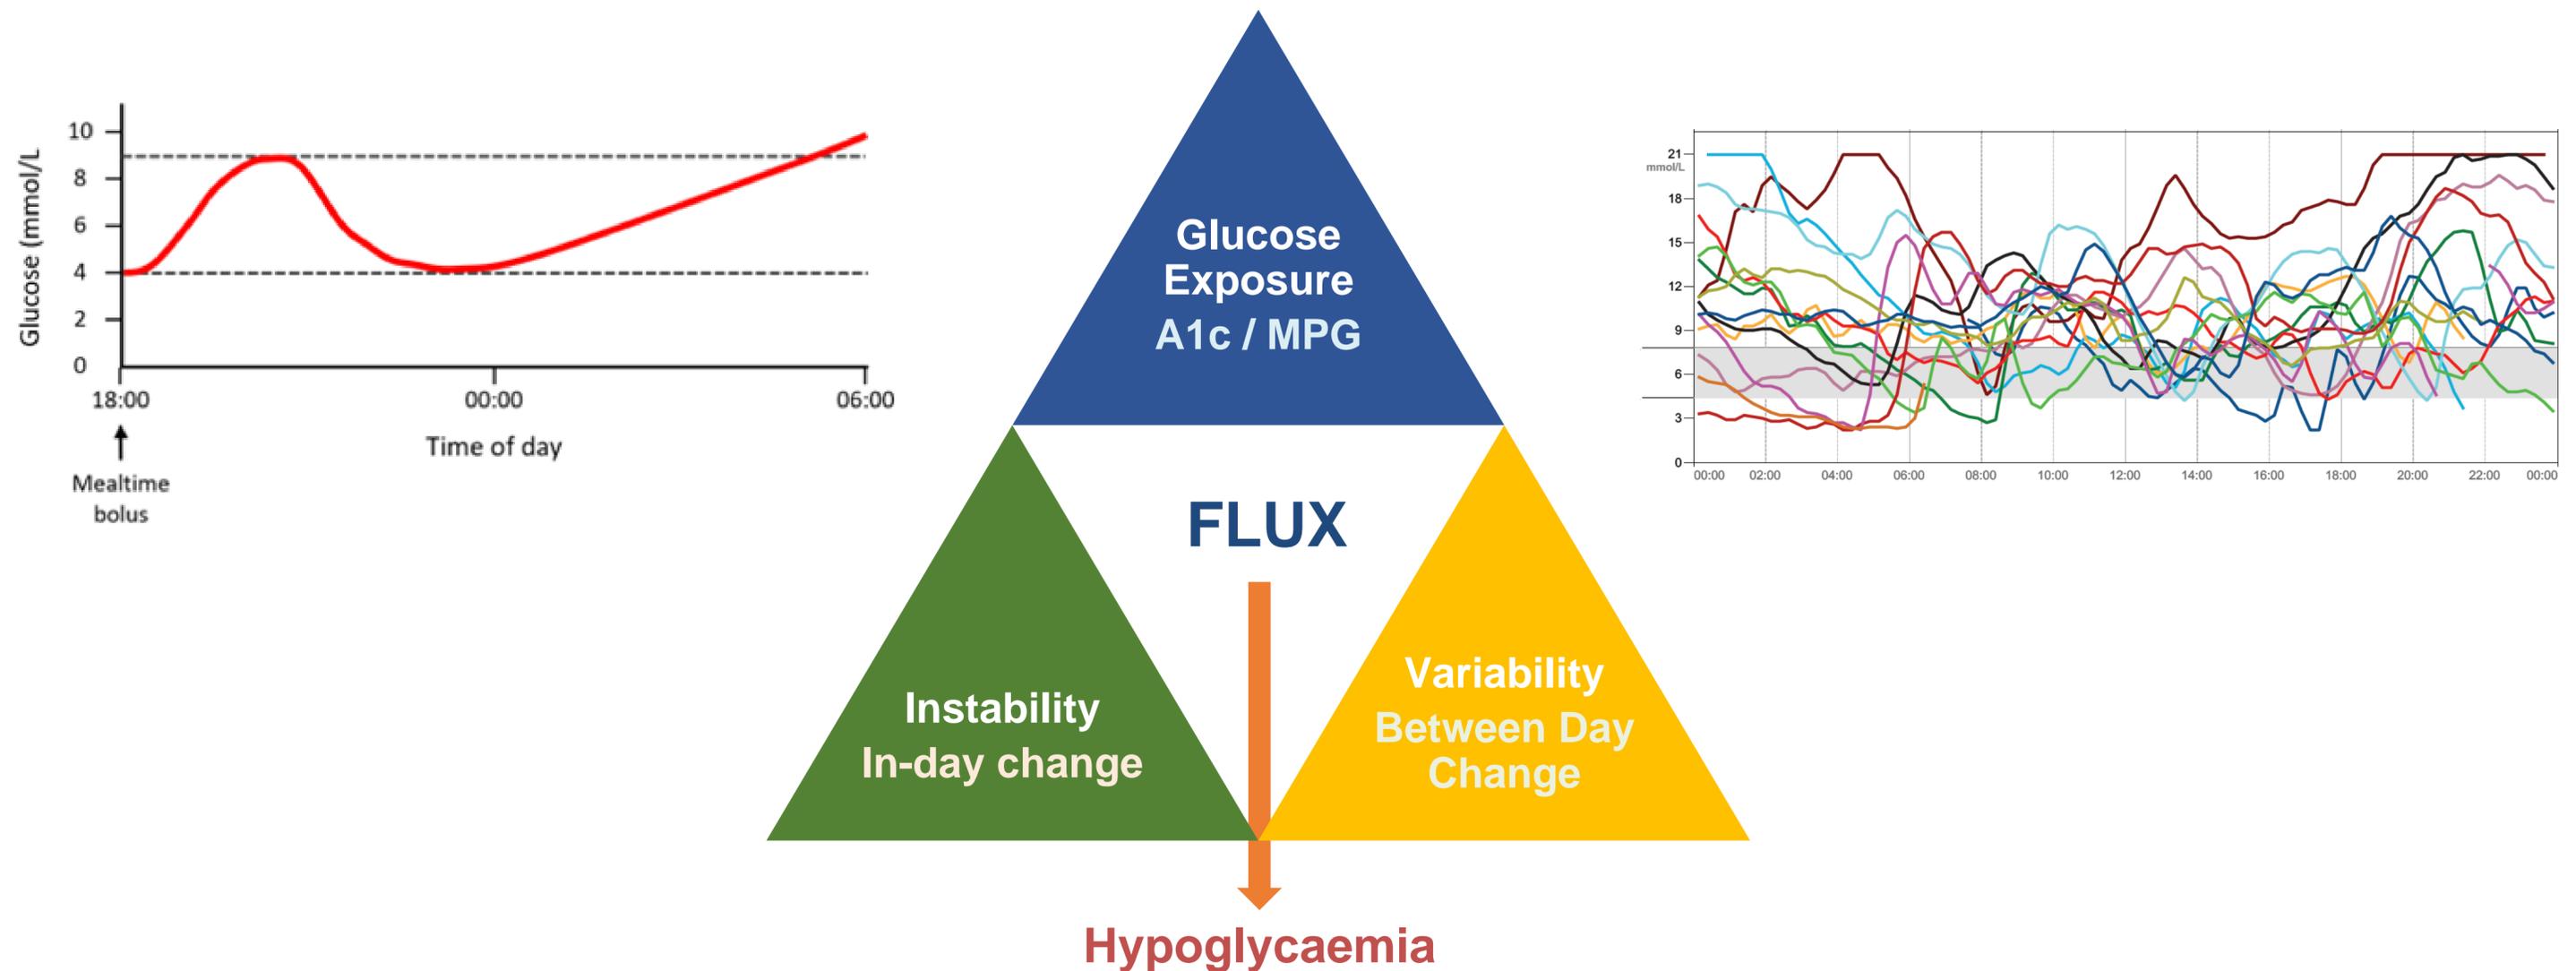

Estimated A1c 6.0% or 42 mmol/mol

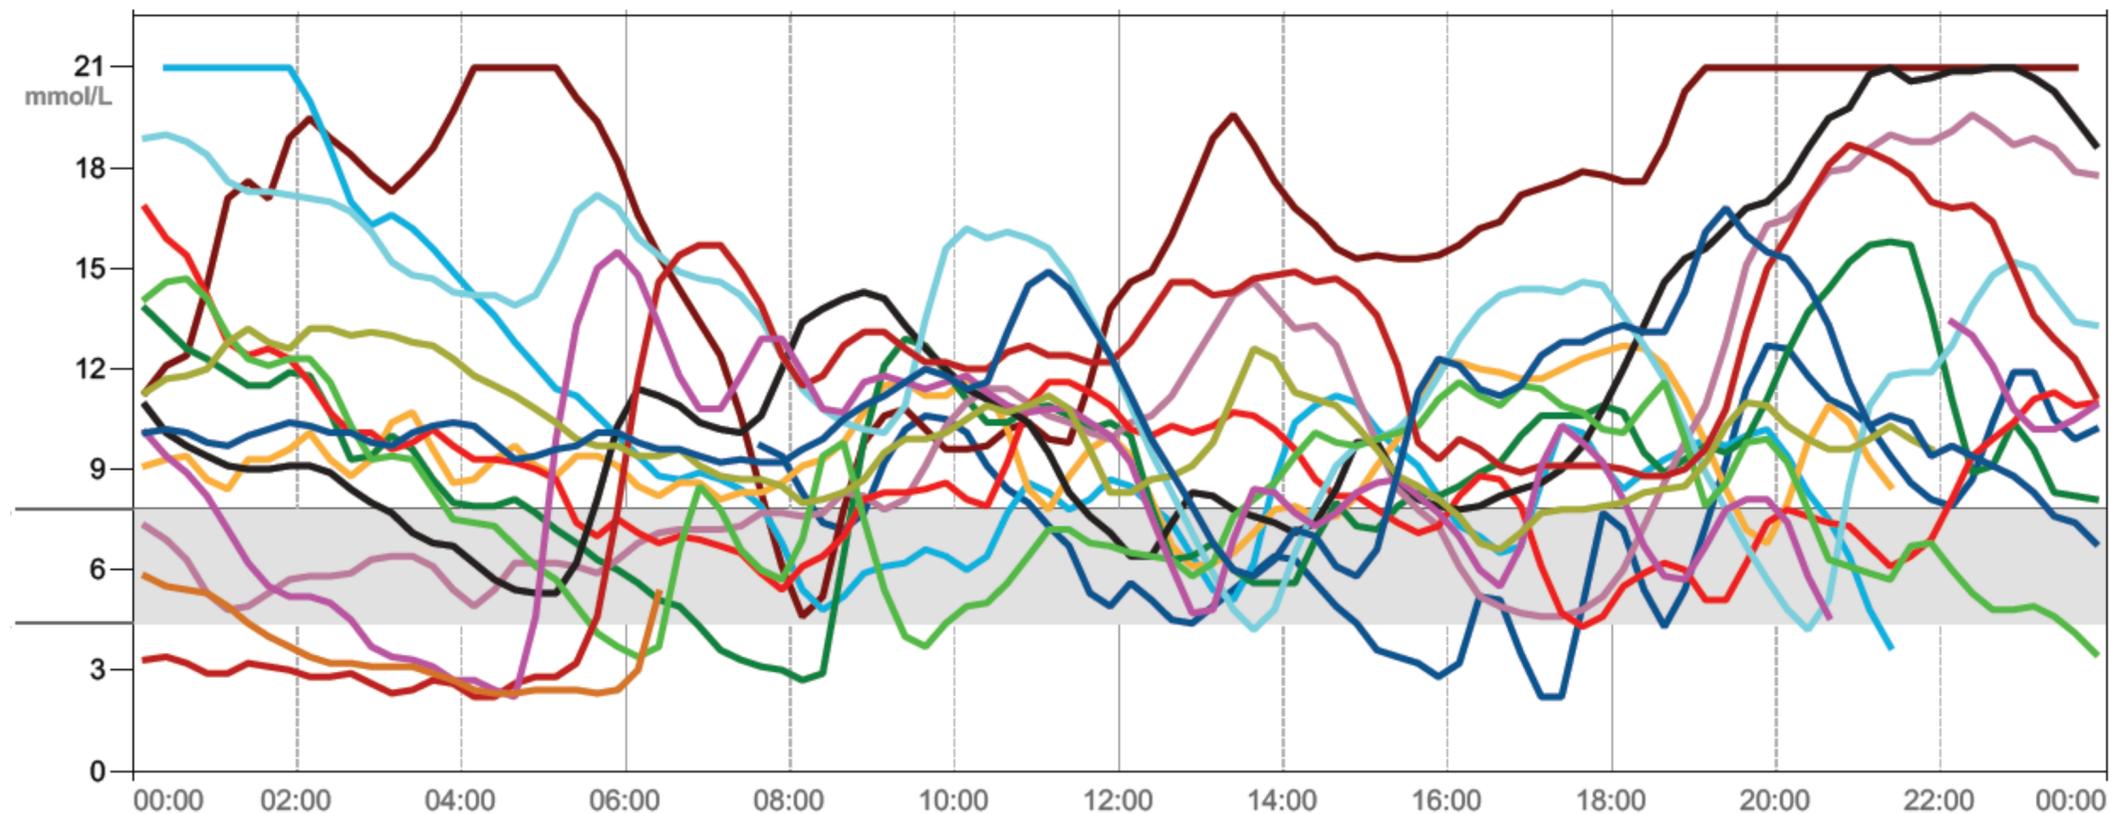

Estimated A1c 6.2% or 44 mmol/mol

Glucose control is more than just HbA1c

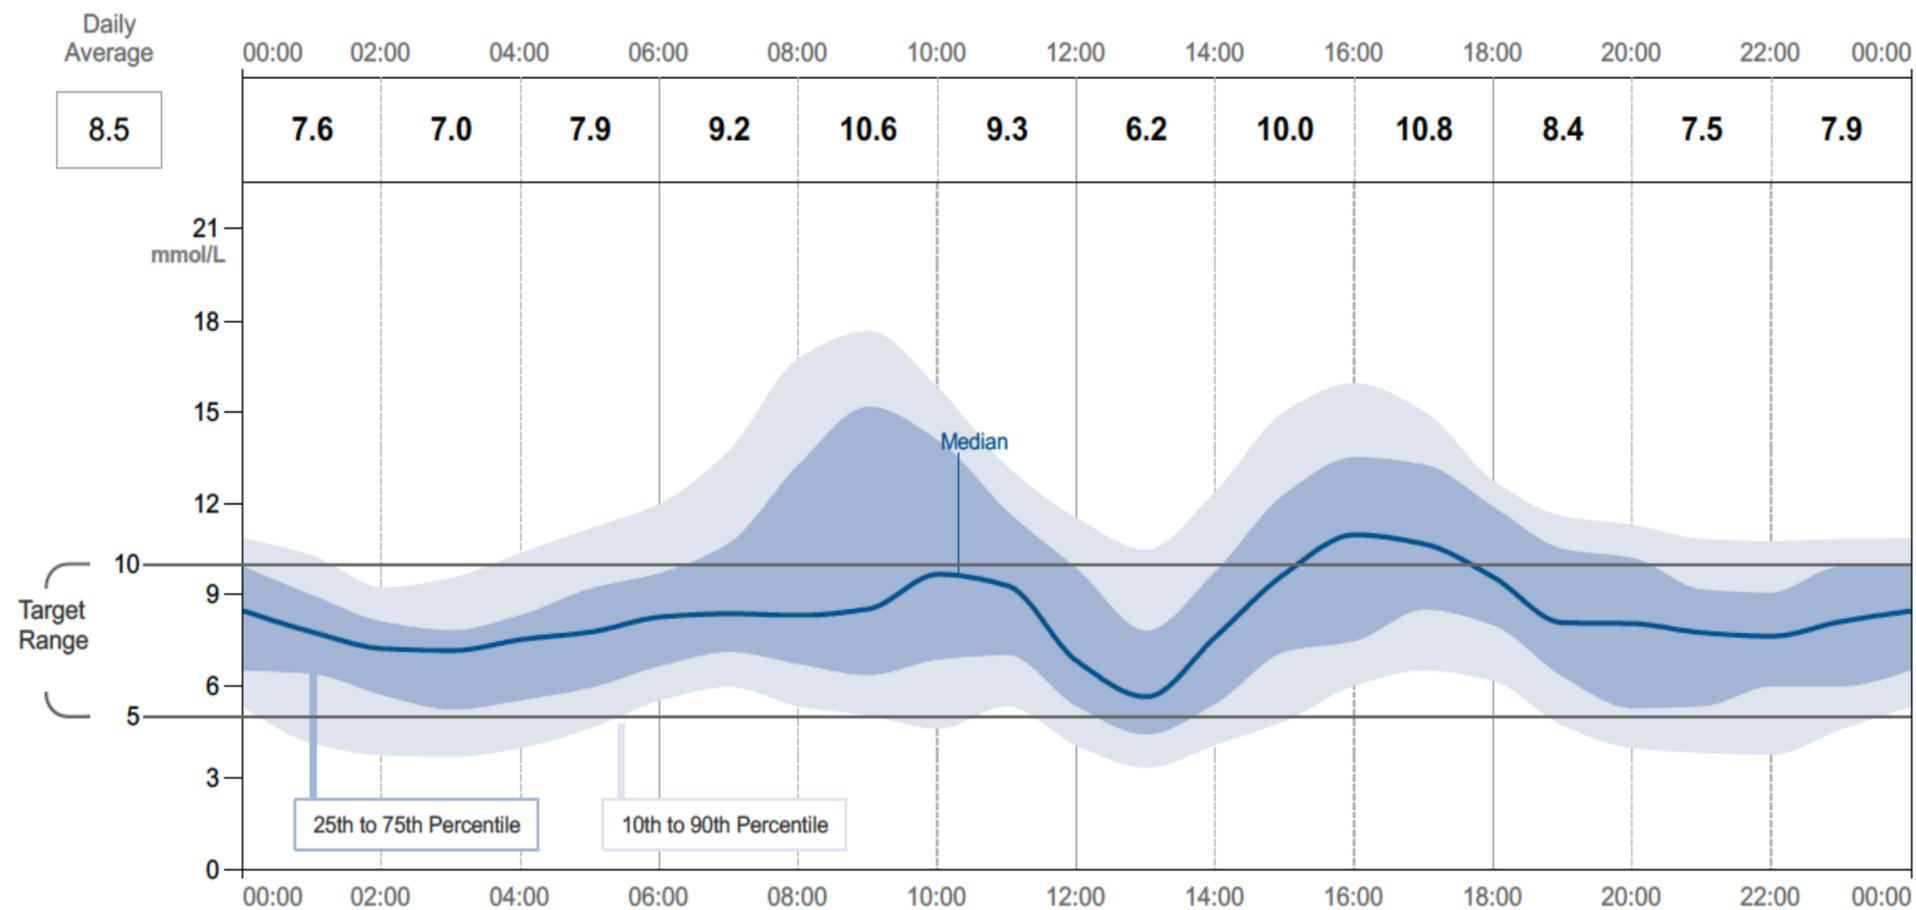

Variability results from different daily instability patterns
but...

Over 2 weeks this can be overwhelming to view on a single image, so an
alternate presentation is required

How does FreeStyle Libre show multiple days?

“The AGP” (daily patterns view)

Estimated A1c **7.0% or 53 mmol/mol**

The AGP is made up of 5 lines;
The 10th / 25th / 50th / 75th / 90th centiles

The darker shaded area (inter-quartile range) represents half of all the readings (ie. those ‘usually’ experienced)

The lighter shaded area (inter-decile range) represents 4/5 of all the readings (ie. those ‘sometimes’ experienced)

The highest and lowest 10% of all readings are left off the image as they represent extreme experience which is unusual

How does variability differ from exposure?

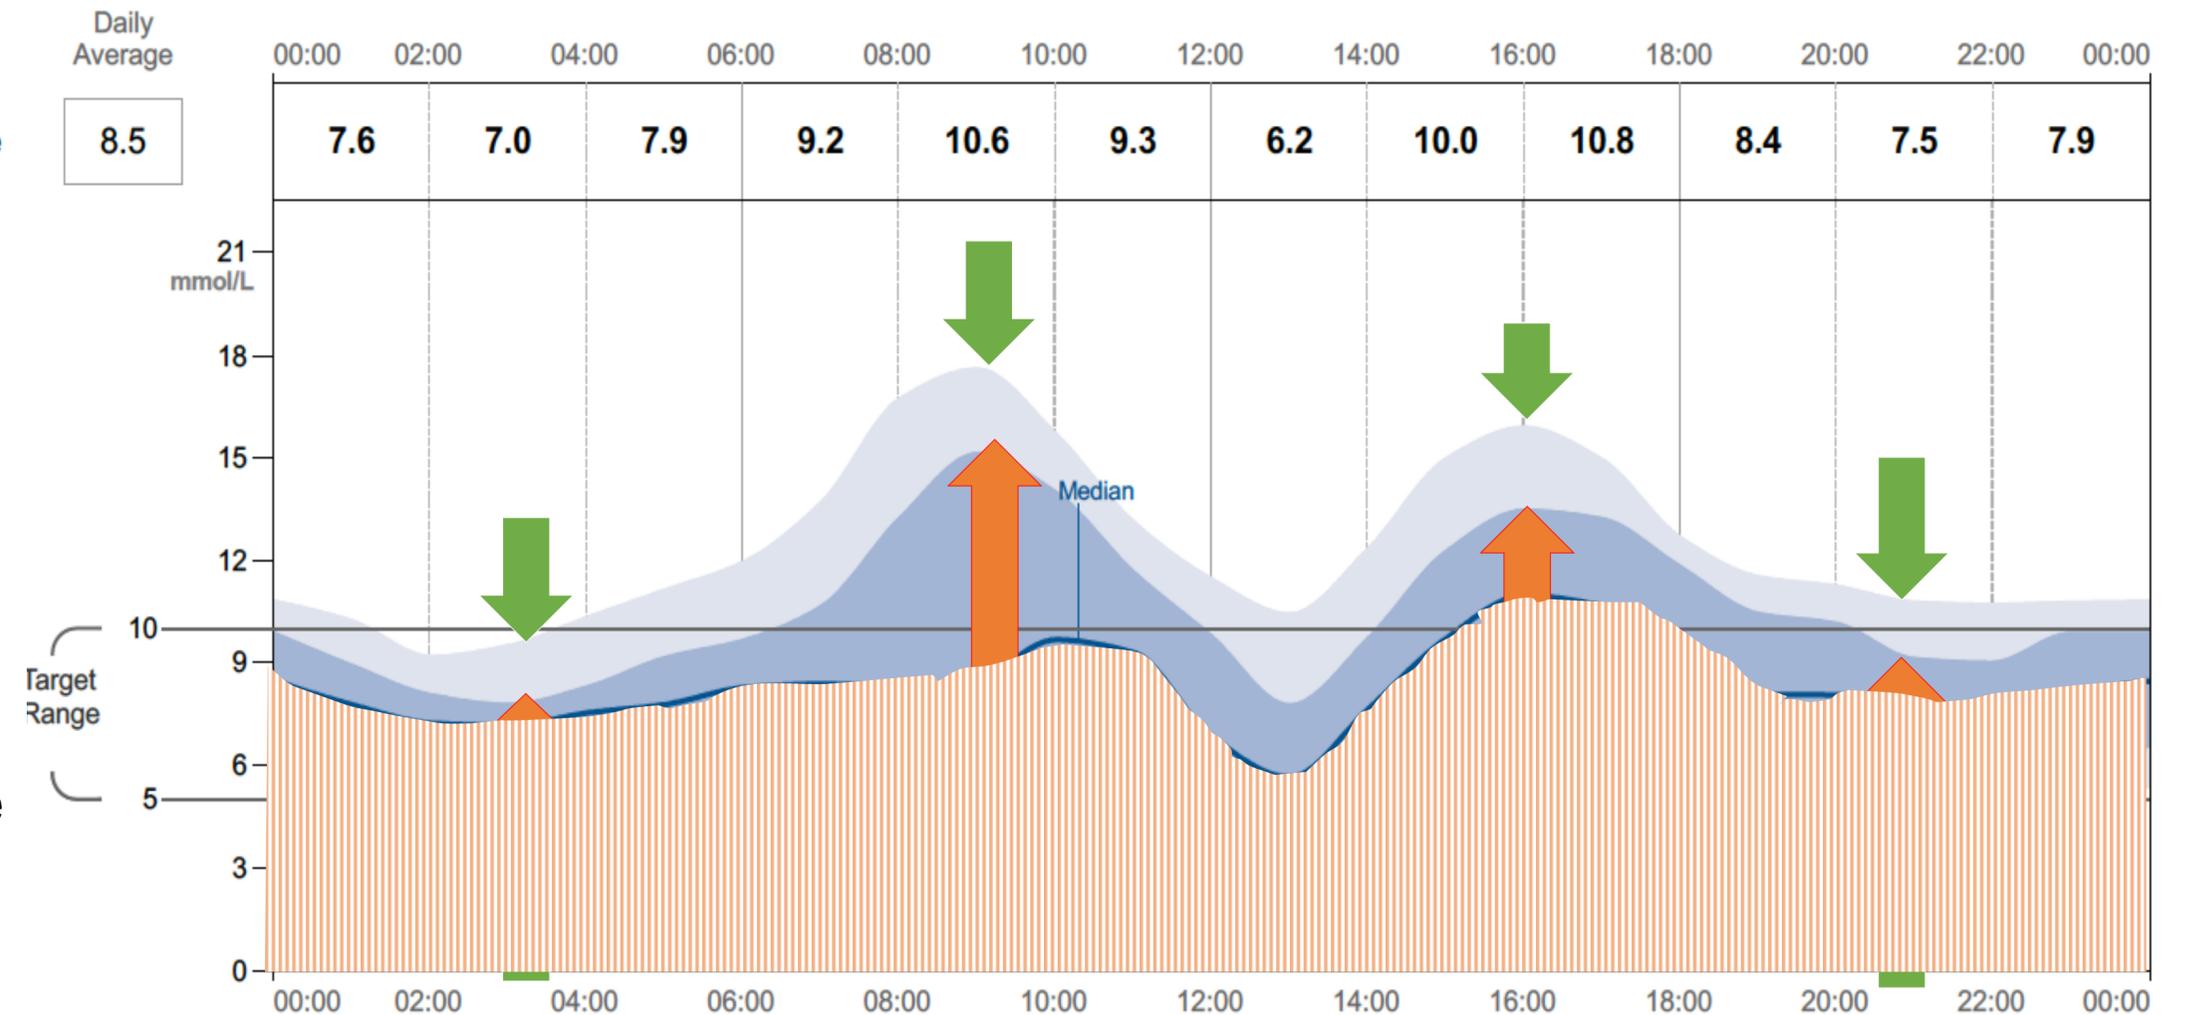

Estimated A1c **7.0% or 53 mmol/mol**

The width of the area shaded dark blue represents usual variability

The width of the area shaded light blue represents occasional variability

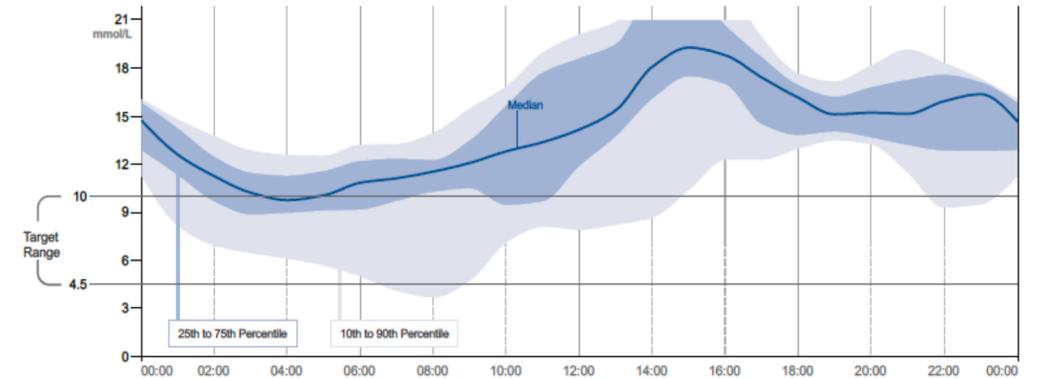

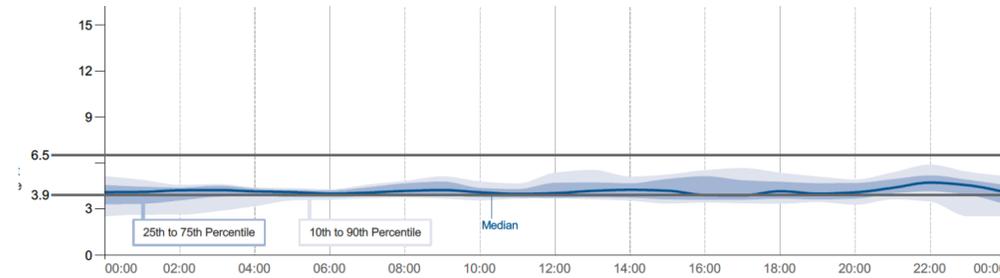

The area under the median line represents the same as the average

The estimated A1c is calculated from this

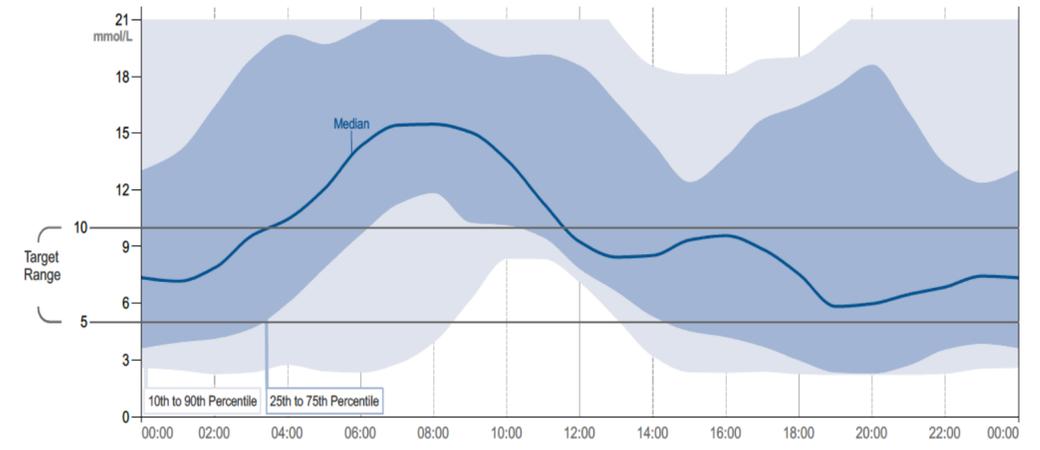

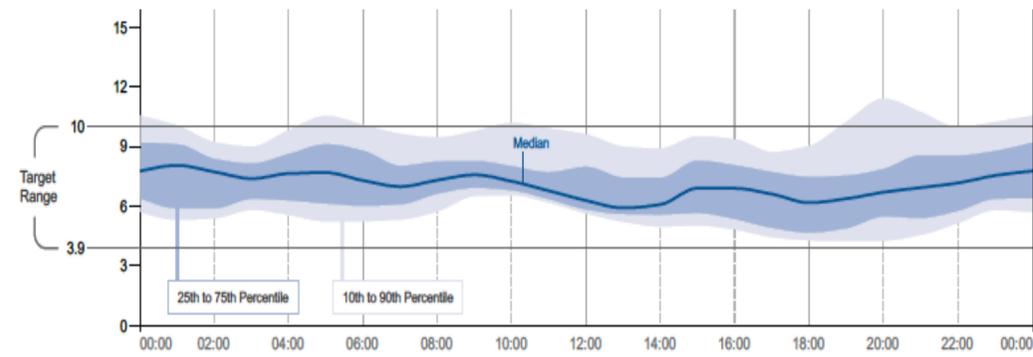

What does variability look like on the AGP?

Non-diabetic

Good Control

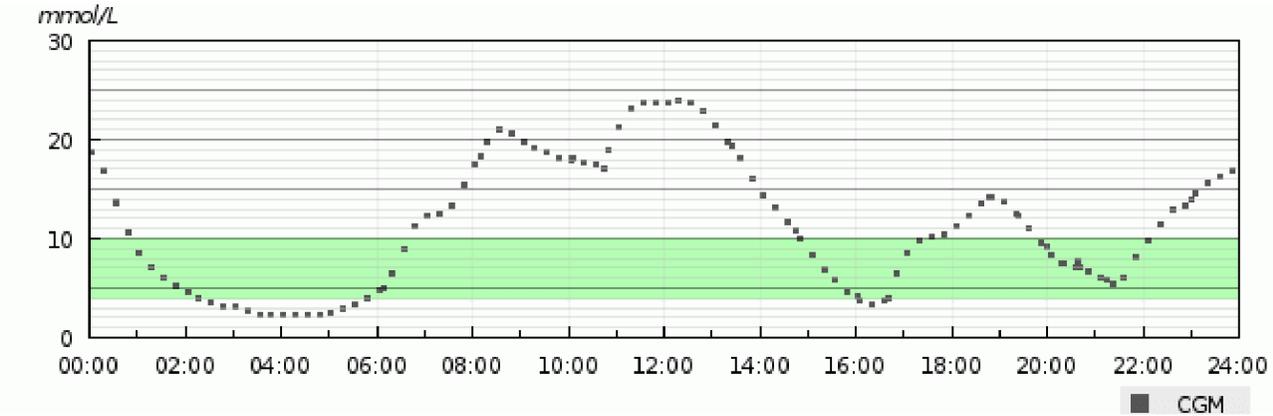

Speaker's Data

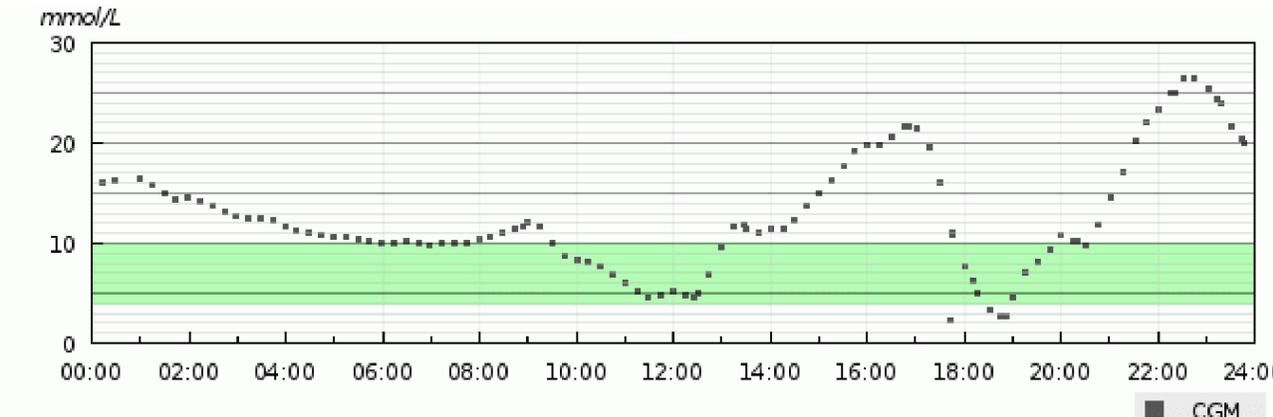

So, if between-day variability results from different patterns of instability each day...

What could be causing that instability on these days, and why is it different between the 2 days?

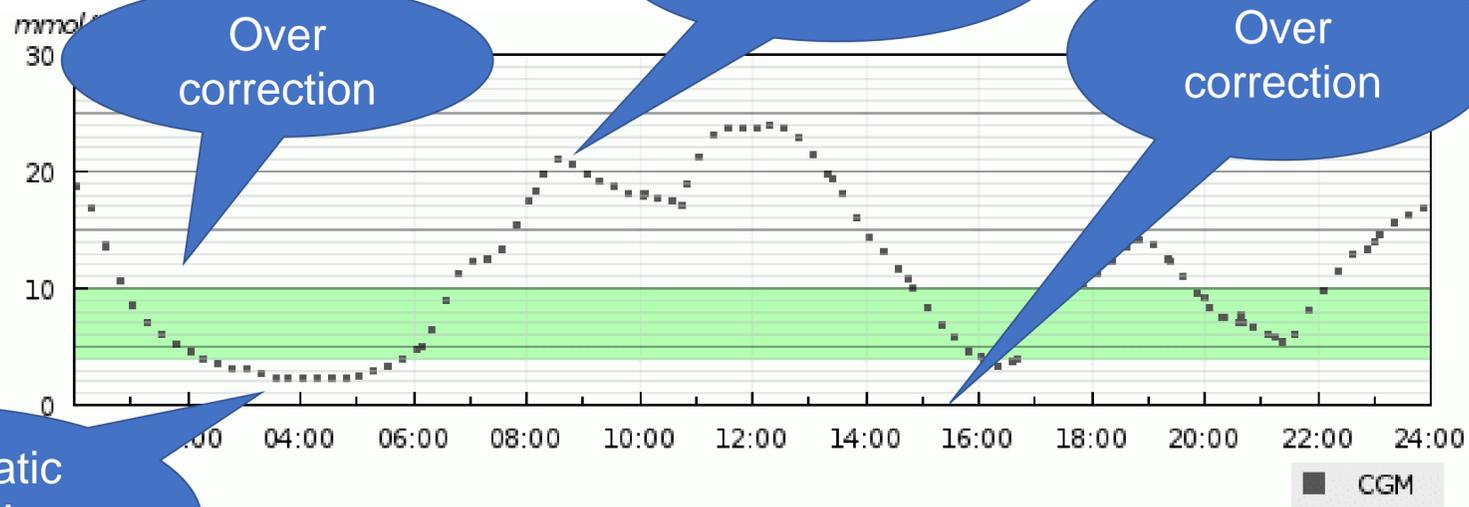

Wednesday 11/5

Tuesday 10/5

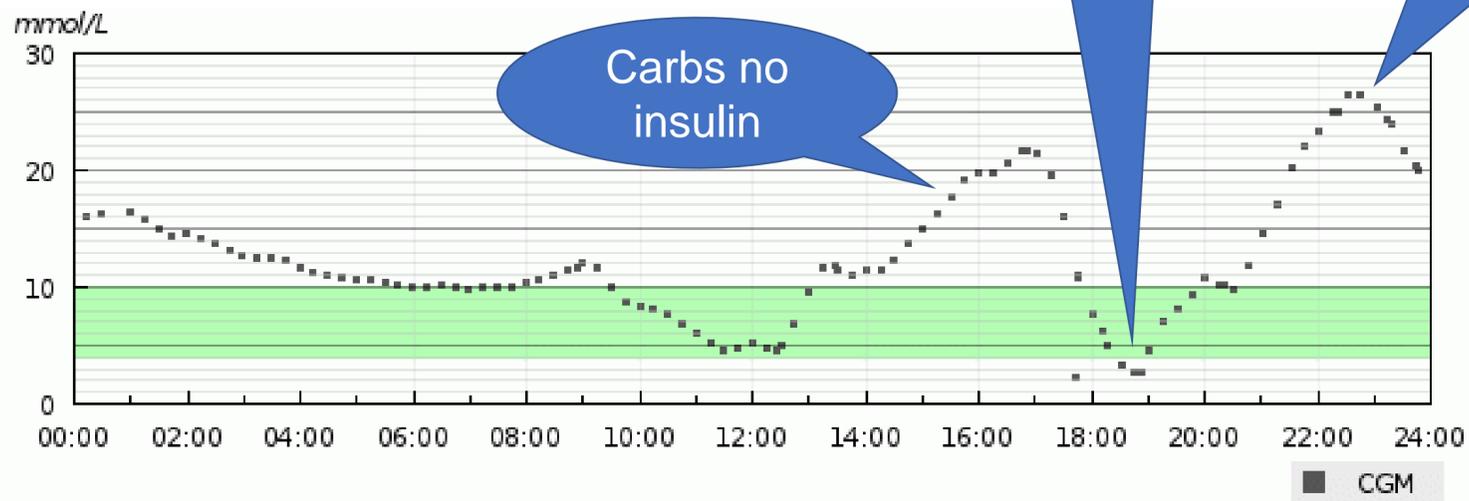

Wednesday 11/5

Asymptomatic nocturnal hypoglycaemia

Tuesday 10/5

Some other causes of fluctuation...

- Insulin Mismatch
- Co-morbid Illness
- Other medications
- Injection technique / needles
- Injection sites / lipohypertrophy
- Injection timing
- Physical exercise
- Stress
- Meal composition
- Carbohydrate counting errors
- Excessive correctional insulin
- Hypoglycaemia
- Fear of Hypoglycaemia
- Insulin omission / duplication
- Alcohol / recreational drugs
- Menstrual Cycle / Pregnancy

... and many more!

Association of British Clinical Diabetologists

How can I assess (& address) this?

Making a plan to address variability

- To see variability you have to look at a series of days (after the event)
- The logical time to do this is at the end of one sensor whilst waiting for the next to warm up (ie in the hour “start up” period)
- Look on a PC or tablet (use Libre or LibreView software)
- Do not worry about the numbers, instead...
- Look at the daily patterns graph (AGP) as a **picture** and ask yourself:
 - How does this picture compare with an “ideal” ?
 - Which bits of the day show the greatest difference from that ideal?
 - What decisions do I make at that time of day?
 - What could I try to do differently in the next 2 weeks to change that?
- Don't be scared to discuss with your HCP if you're out of ideas

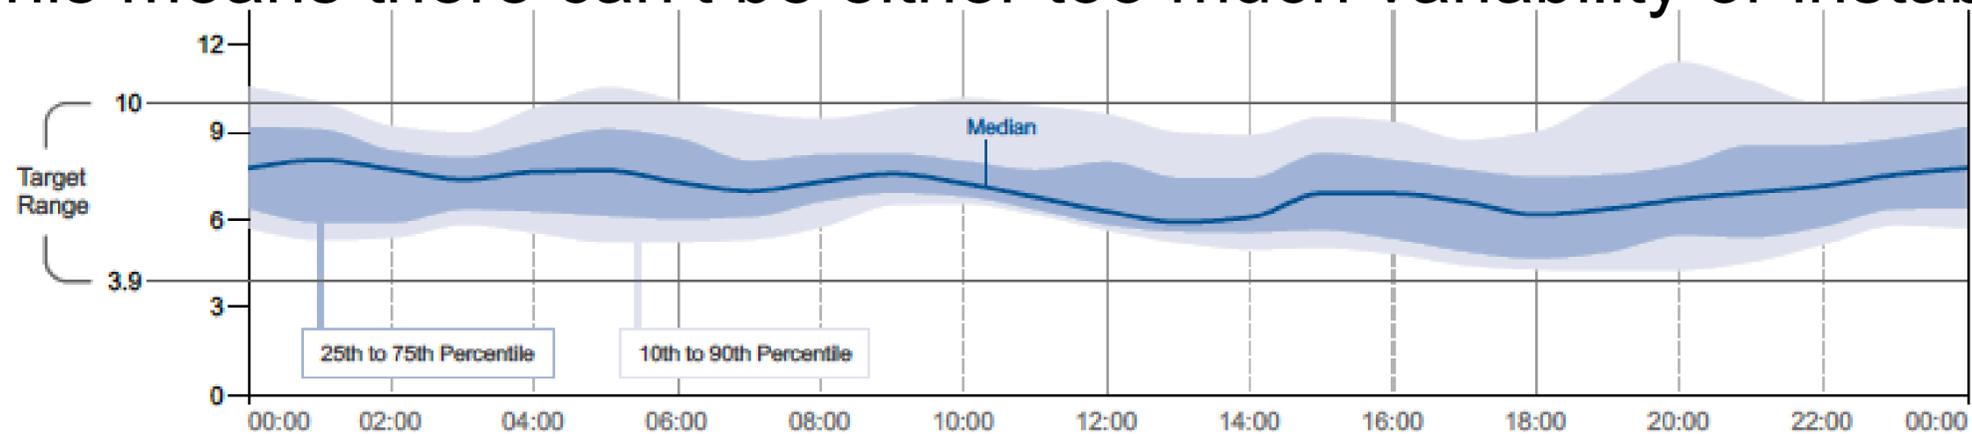

What's ideal?

An AGP Representing 'Good Diabetes Control'

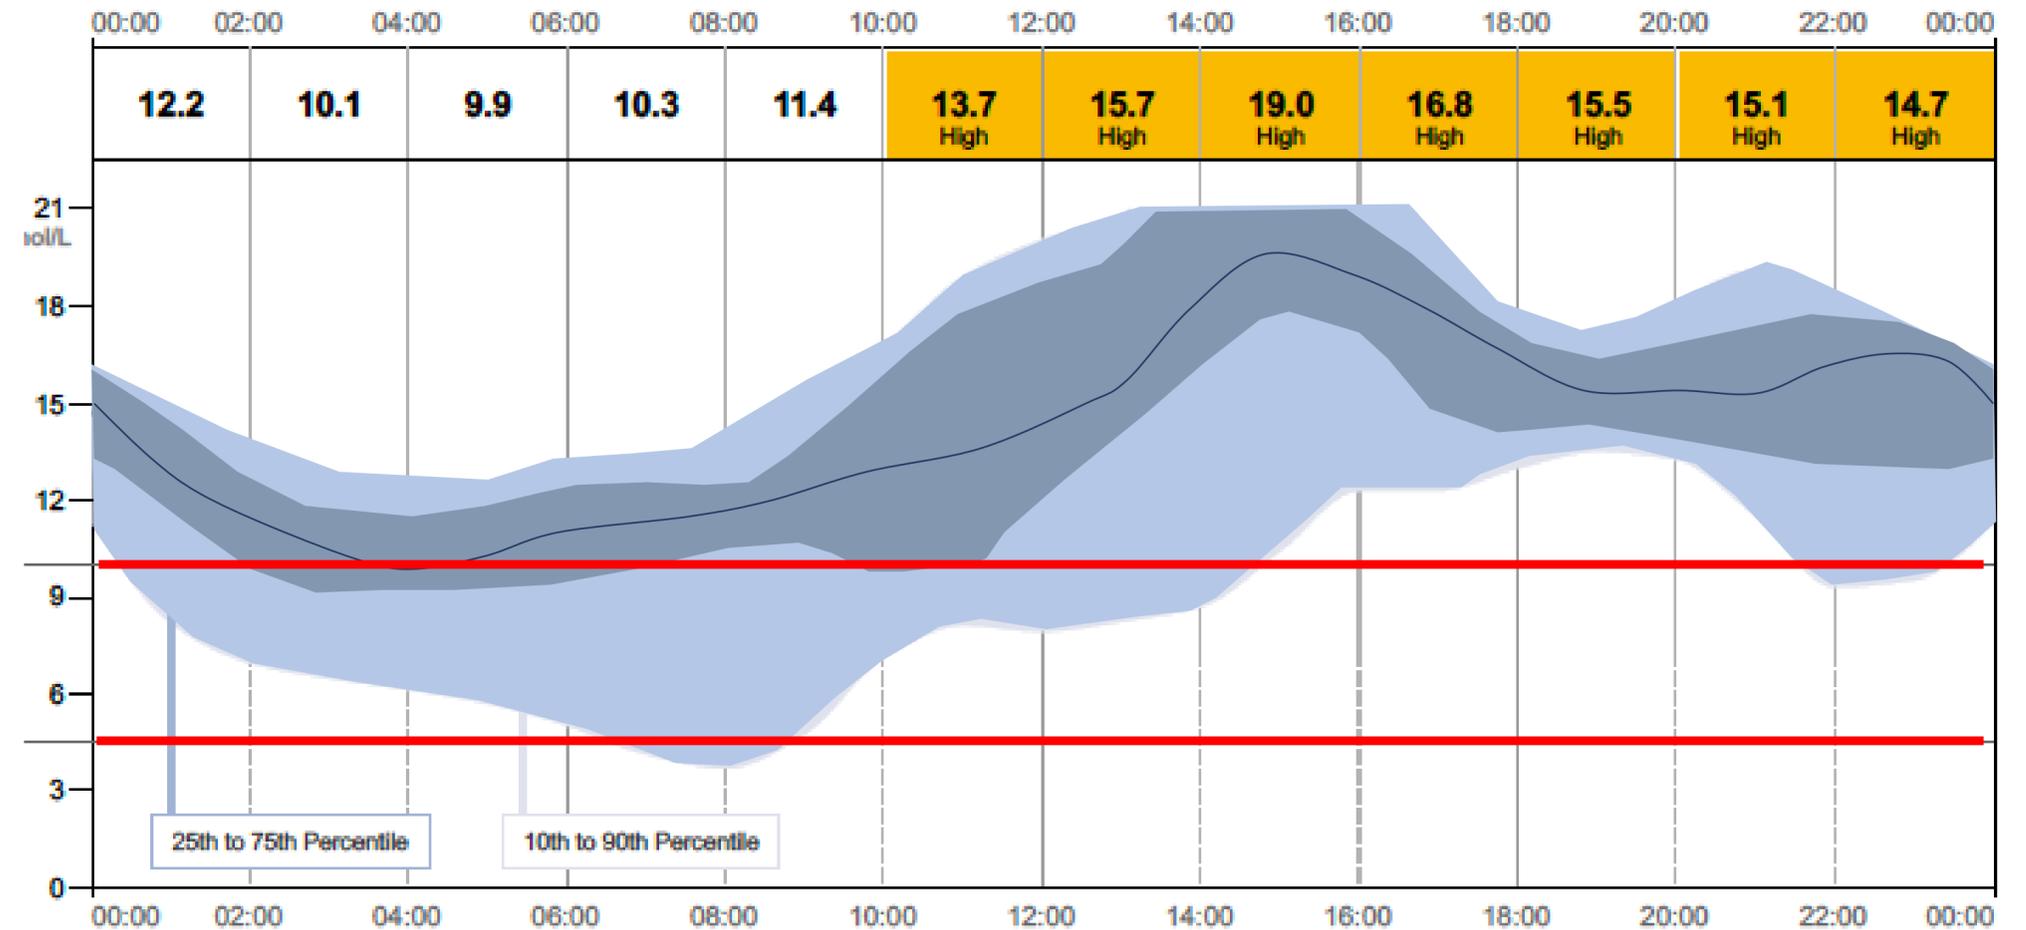

As much of the blue shape as possible should fit inside the "target range" Box between 4 and 10mmol/L

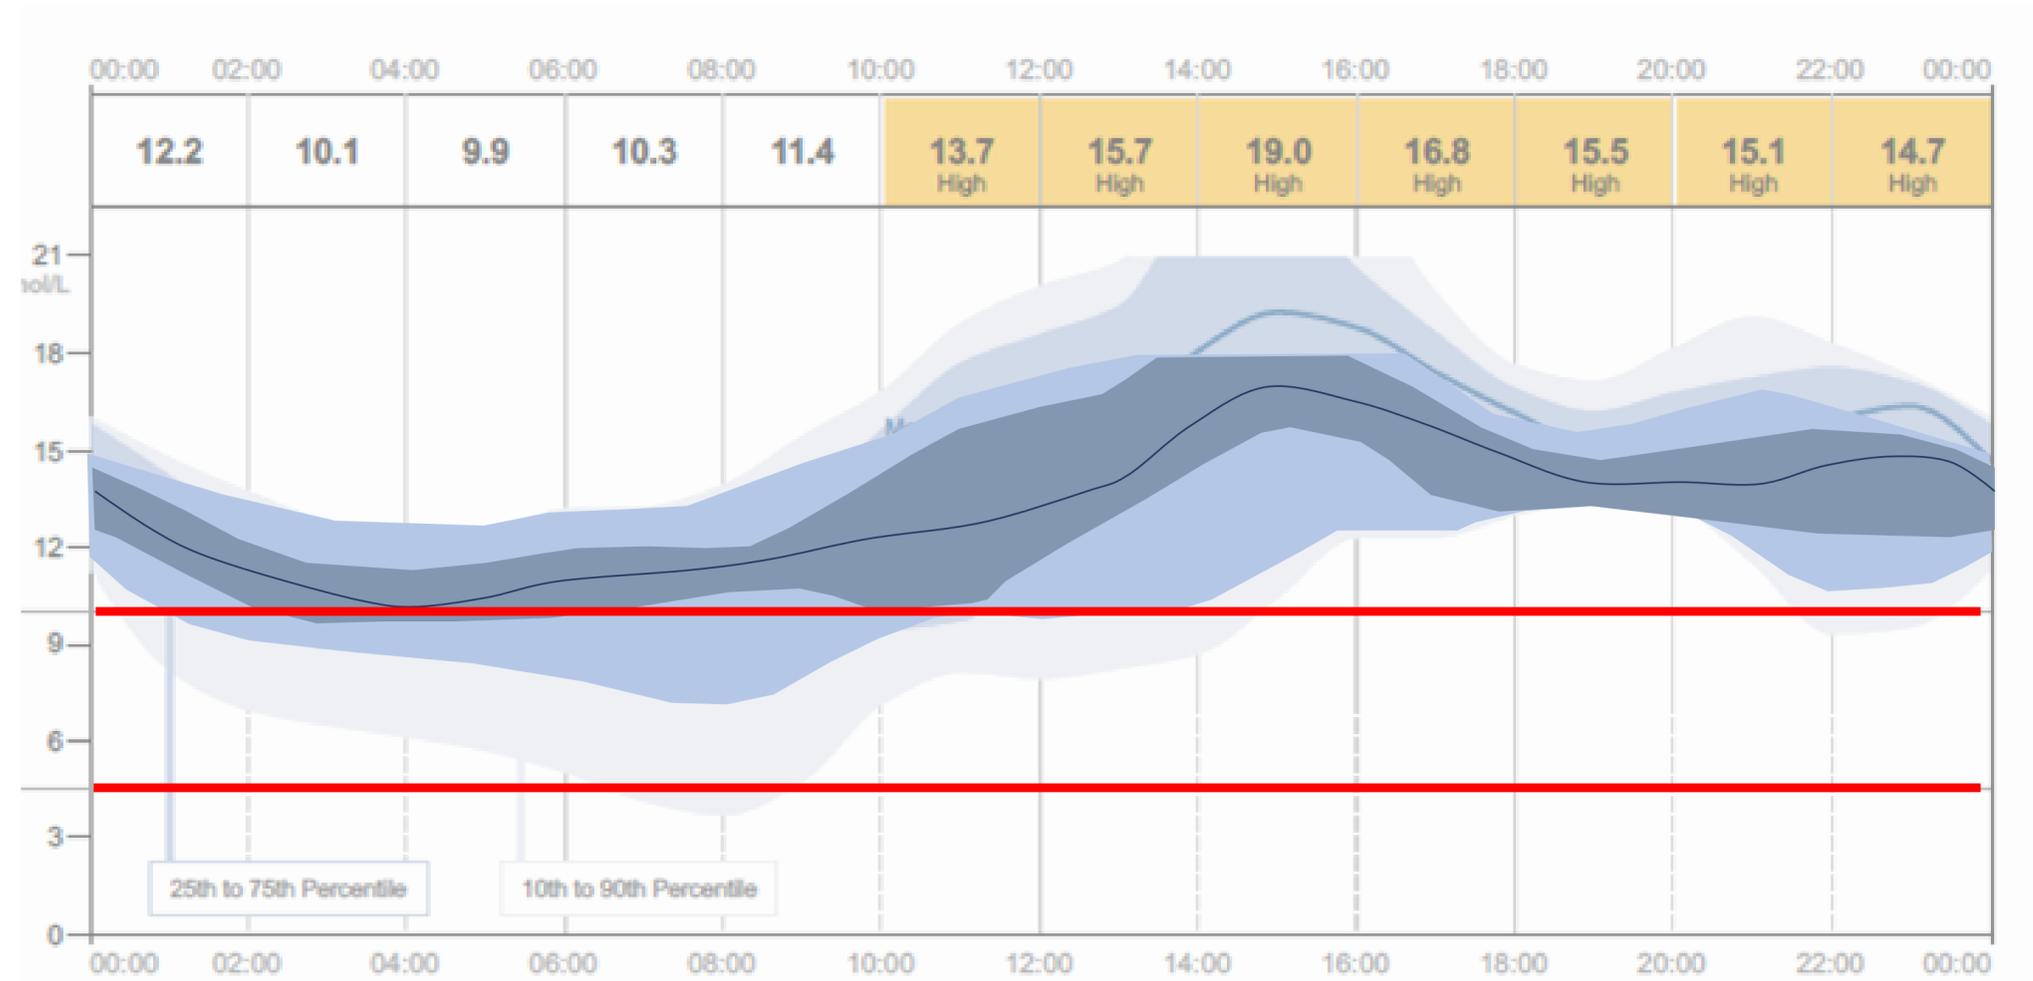

This means there can't be either too much variability or instability

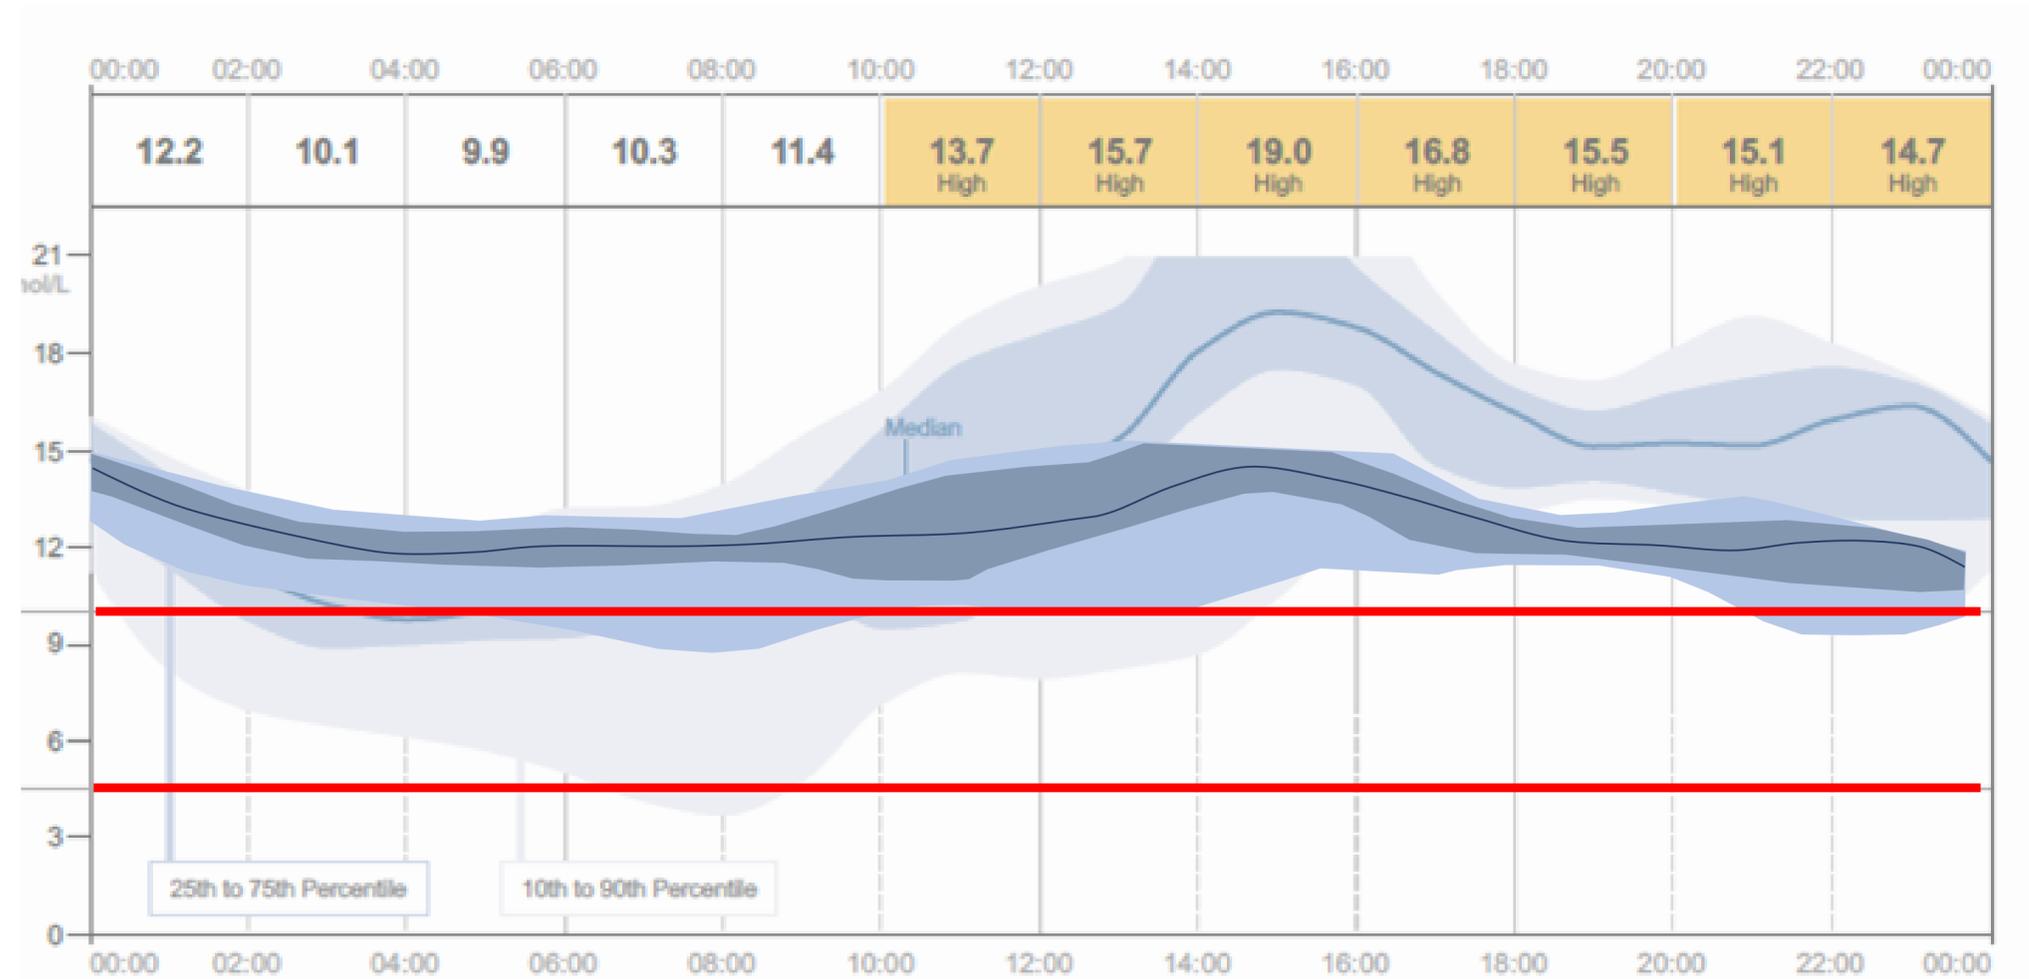

So, how does this picture need to change?

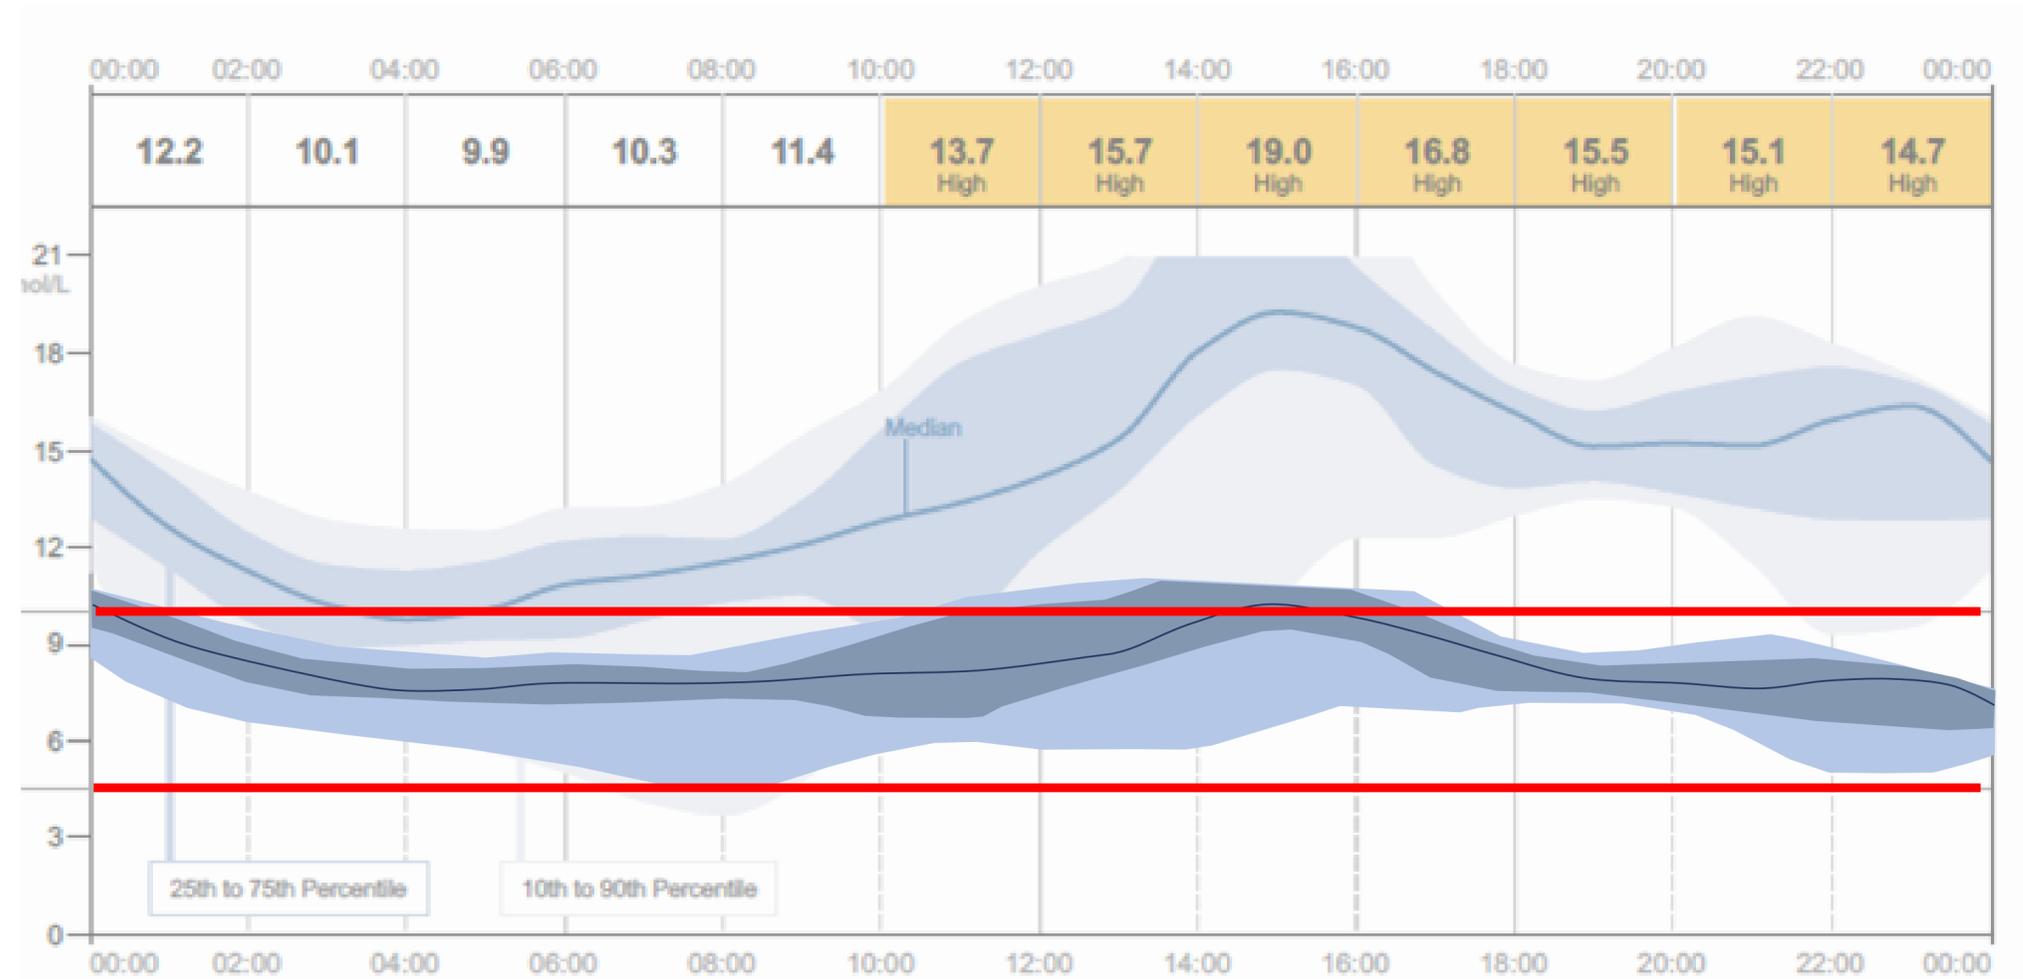

1 First...reduce variability (narrow it)

- 1 First...reduce variability (narrow it)
- 2 Then...improve stability (flatten it)

- 1 First...reduce variability (narrow it)
- 2 Then...improve stability (flatten it)
- 3 Then reduce exposure (lower it) which will often happen on its own after 1 and 2

An example: Andrew

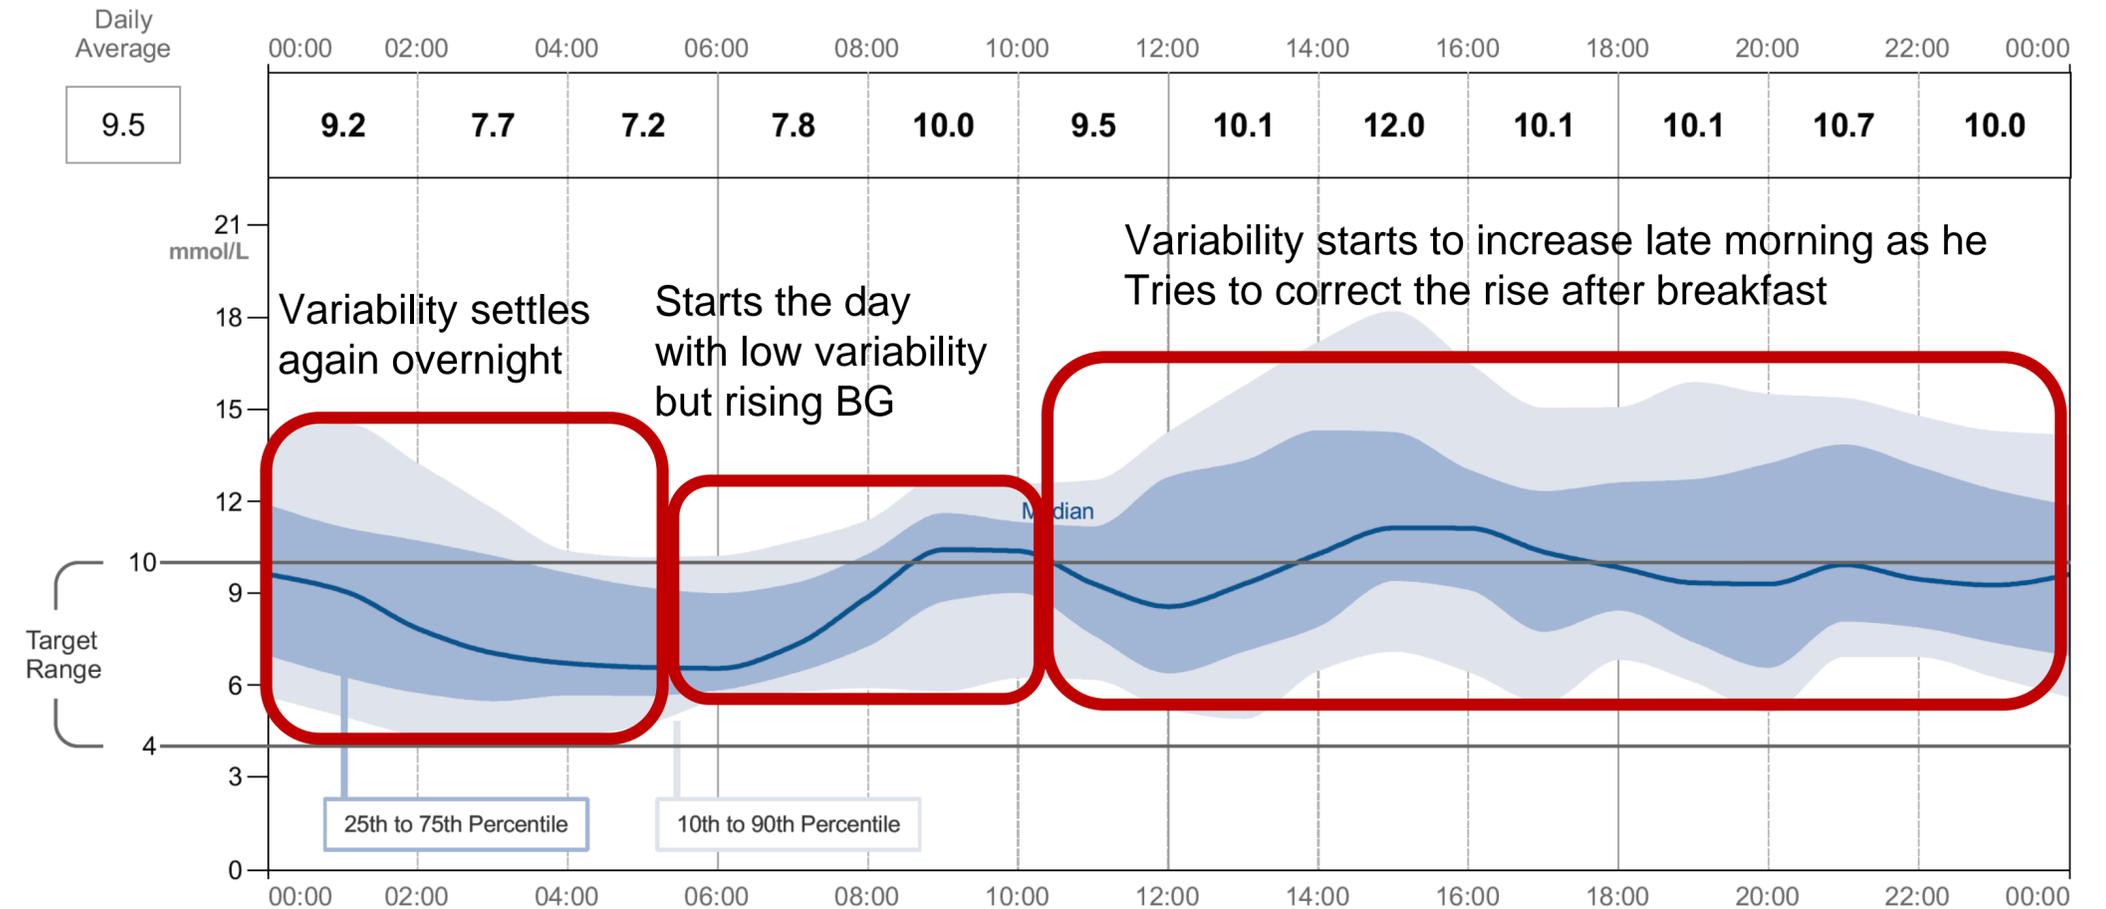

- 44 yr old man
- Type 1 diabetes since aged 11
- HbA1c for last 5 years in 7.5 – 8.5% range (most recently 8.3%)
- Treatment with basal/bolus MDI (Lantus/Humalog; DAFNE graduate)
- 28 units Lantus / I:C 1:10 & ISF 1:3 (TDD 50-55units)

Association of British Clinical Diabetologists

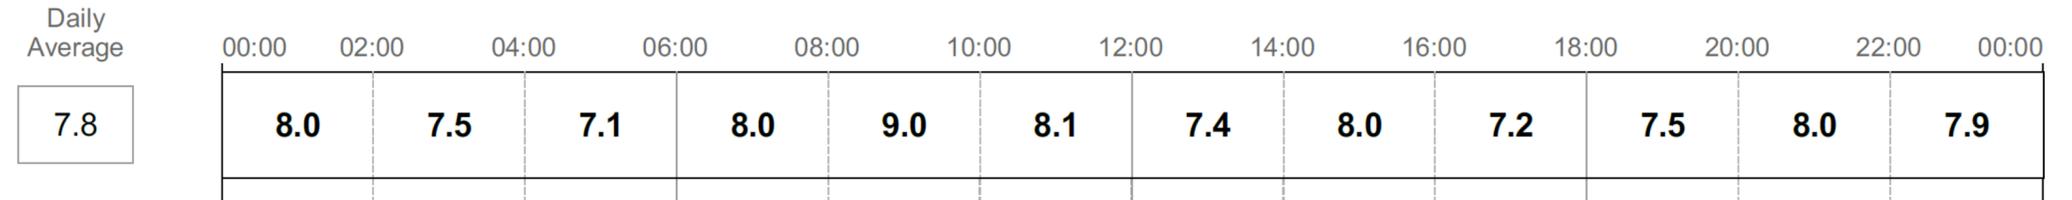

1st 2 weeks sensor wear

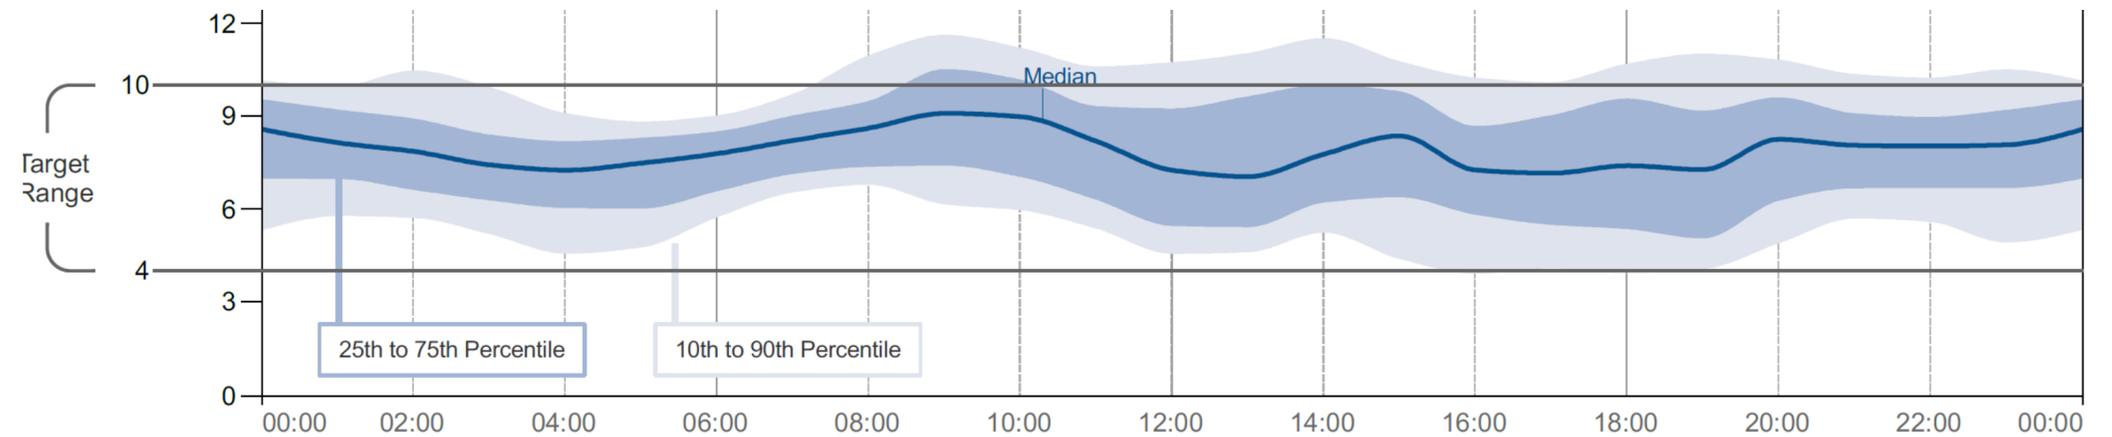

So, if his BG levels did not rise with breakfast then he wouldn't need to correct and his variability might remain low

ACTION therefore → increase insulin:carb ratio at breakfast

1 month after intervention

This is now a near ideal profile - his afternoon and evening variability have greatly reduced and this has allowed him to achieve a lower HbA1c without risk of hypos

It has stayed like this ever since (last 2 years)!

Summary

- Glucose variability is important because it gets in the way of achieving overall glucose-related goals
- Variability increases the hypo risk
- Reducing variability is often the first step to improving overall control
- To see variability use the Daily Patterns Profile (AGP)
- Make a habit to look at the end of each sensor
- Decide on one change to make if the picture does not match your ideal and review in another 2 weeks
- Discuss with your HCP if not making progress!
