Review of acute management of Hyperosmolar Hyperglycaemic State in an acute hospital

E Burn 1, Giddings J 1, Higgins K 2, Patel N 3

¹ Geriatric Medicine Registrar, ² Consultant Diabetologist, ³ Consultant Acute Physician

University Hospitals of Leicester NHS Trust

Background

Hyperosmolar Hyperglycaemic State (HHS) is a medical emergency, usually affecting older people with high associated mortality. Diagnosis should be prompt and treatment intensive whilst adjusting management for the complex multi-morbid patients in which it presents.

The aim of this audit was to review the diagnosis and management of HHS and compliance with the trust protocol.

Methods

A retrospective analysis was undertaken using electronic and paper records using the Joint British Diabetes Societies guidelines (2012) for audit standards.

Insulin	Already use	8	47%
	Basal doses continued while on FRII	4 (of 5)	80%
	Held mixed insulin while on FRII	2 (of 3)	66%
Commenced or	13	76%	
VTE prophylaxi	is	15	88%
IV antibiotics		10	59%
Foot review		8	47%
Place of care	- ACB (Level 1A)	6	35%
	- Other ward then ACB	5	29%
	- Non-ACB	6	35%

Outcomes

(2)

77% were managed on a monitored unit, but only 47% directly from ED. At the point of discharge insulin was commenced in 29% and increased in 24% where the HHS diagnosis was documented on the discharge letter in 65%. Half of the patients had a length of stay greater than 7 days (mean 10 days and range 1-48 days). There is significant associated mortality with death of 35% within 6 months of admission.

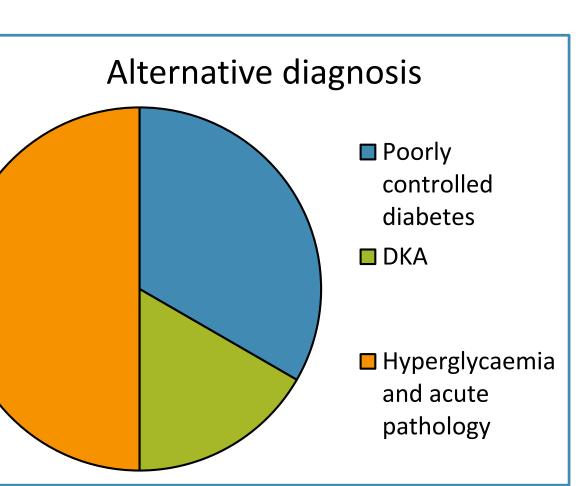

- (1) The calculation of osmolality
 - Escalation of care to HDU/Level 2 care
 - Intravenous fluid replacement with 0.9% sodium chloride, with potassium as required
 - Monitoring of glucose, sodium and osmolality to guide management
 - If significant ketonaemia is not present, to not start insulin
 - Assess for infection
 - Ensure VTE prophylaxis (or alternative) is given
 - Foot assessment and minimise risk of pressure damage

The data set was complied from the last 30 patients coded as HHS by the emergency department.

<u>Results</u>

30 patients were initially selected where 13 had an alternative diagnosis, creating a sample of 17 patients.

Of the non-HHS group 10 patients had no osmolality calculated. On review, the trust hyperglycaemia or DKA protocols would be more appropriate.

The cohort (n=17) was predominantly older females with known diabetes and a high comorbidity burden. 65% were female with an average age of 74.5 years.

ADUL PRESO	CRIPTION CHART			Univ	ersity Hos	preais or	NHS Trust
		 ESTABLISH DIAGNOSIS OF HHS High blood sugars > 30mmol without significant ketonaemia (blood ketones <3mmol/L or ketonuria < 2+) or acidosis (pH>7.3) High Osmolality > 320mosmol/kg (calculated serum osmolality = 2Na⁺ + glucose + urea) Hypovolaemia 					
Patient's addressograph		If Type 1 diabetes or hyperglycaemia with acidosis (pH <7.3 or bicarbonate<15) AND ketones present (blood ketones>3mmol/L or ketonuria >2+) FOLLOW DIABETIC KETOACIDOSIS (DKA) PROTOCOL For more information refer to UHL guidelines on HHS management. Diagnosis

Diagnosis was made at 2.07 hours from arrival with the majority satisfying the criteria of BM > 30 without significant ketonaemia, high osmolality and hypovolamia.

BM > 30	13	77%
Ket < 3	16	94%
pH > 7.3	17	100%
Osmolality>320	15	88%

Osmolality was calculated in 88% at diagnosis. 71% had initial fluid resuscitation documented, but there was a paucity of ongoing fluid balance monitoring.

77% of patients had HbA1c measured pre-admission (mean 8.7%, mean 94 days prior). Only 24% had HbA1c checked on acute admission where all readings were greater than 8%.

Monitoring

The HHS management proforma was commenced in 12 of 17 but continued for only 5 patients with significant omissions, chiefly in fluid management. Not one patient has a repeat osmolality. Reasoning for intravenous insulin varied, 31% were used prematurely.

Early diagnosis and recognition of HHS including rigorous adherence to protocols are key in minimising morbidity and mortality. This audit showed that initial management was satisfactory however on-going adherence to protocol was poor as was the prognosis for this group of patients.

Further action is required to raise awareness of HHS diagnostic criteria and the importance of on-going active management. Technology could be used to prompt the calculation of osmolality in hyperglycaemic admissions and at intervals if HHS is confirmed. There also should be a robust follow-up pathway at discharge.

Recommendations

- Develop an electronic prompt to review the deteriorating hyperglycaemic patient and calculate osmolality alongside pH and ketones
- Encourage documentation of repeated osmolality to guide management decisions
- Active education, audit presentation and improve familiarity of acute medical staff with the HHS protocol
- All patients with HHS diagnosis should have an early discharge review and managed on ACB (1a level) unless agreed with the diabetes team
- Recognise the associated poor prognosis and to prioritise treatment on quality of life and early escalation discussions
